ACKNOVLEDGMENT

Many agencies and individuals have contributed data for this report. The sources of data presented in Chapter III are noted at the bottom of each page. Particular acknowledgment is made to the following:

City of San Bernardino

City of San Diego

Los Angeles County Flood Control District

Los Angeles Department of Water & Power

Orange County Flood Control District

Riverside County Flood Control and Water Conservation District

San Bernardino County Flood Control District

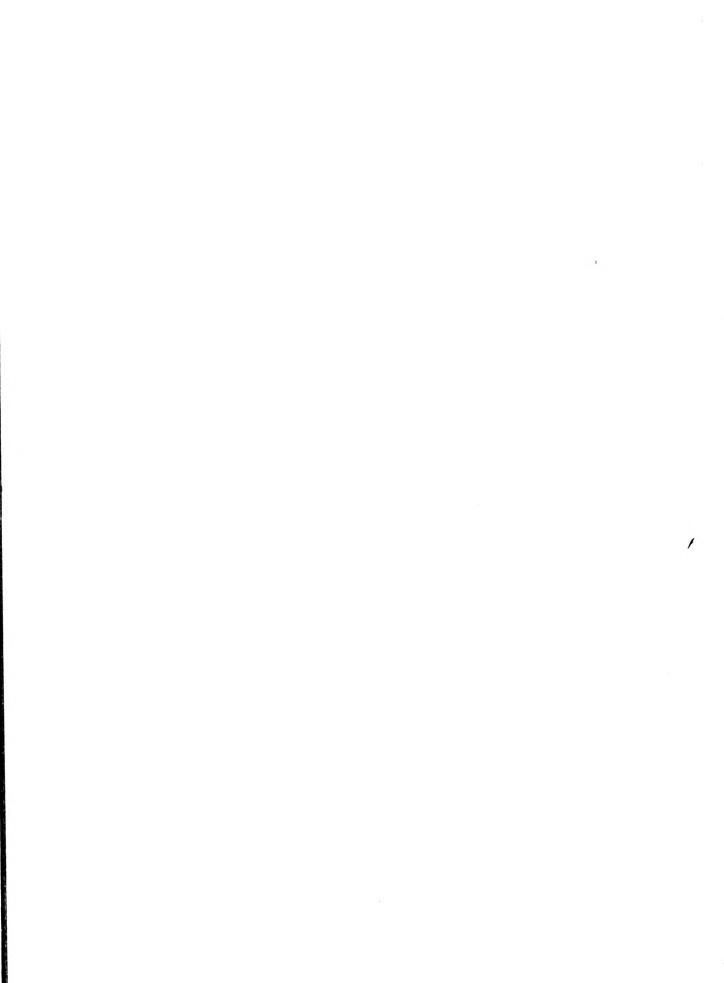

San Bernardino Valley Water Conservation District

The Metropolitan Water District of Southern California

United States Geological Survey

United States Weather Bureau

Without the cooperation of these agencies this report would not be possible, and the Division of Water Resources acknowledges this assistance with thanks.

WATER SUPPLY SUMMARY FOR SOUTHERN PORTION OF CALIFORNIA

1950

CHAPTER I. INTRODUCTION

This report is the twentieth of a series begun in 1932, in recognition of the need for compiling basic data for use in the continuing study of water problems in the southern portion of California. The water problems involved were accentuated during the period covered by the report by subnormal precipitation for the sixth consecutive season. The deficiency in rainfall at Los Angeles for the six-year period from 1944-45 through 1949-50 was 30.87 inches, as compared to a mean seasonal rainfall of 15.43 inches. This paucity of rainfall has been reflected in subnormal runoff in streams of the area. The flow of the San Gabriel River near Azusa was only 23.1 per cent of the long-time mean during 1949-50.

This extended drought, accompanied by a continued, rapid increase in population, has created a serious water supply shortage in areas where imported supplies are not available. Difficulties in providing sufficient water for municipal use were experienced by the Cities of Santa Barbara, Ventura, and San Diego. Reservoirs of the latter city had been depleted to about 19 per cent of their total capacity by October 1, 1950, and storage in the majority of the other conservation reservoirs in the South Coastal Area was dangerously low.

Importations were continued from Owens River and Mono Basin by
City of Los Angeles, and from Colorado River by The Metropolitan Water
District of Southern California. Approximately 164,000 acre-feet of Colorado

River water were delivered during the water year 1949-50, which was the maximum annual amount delivered through that date and an increase of slightly more than 13,000 acre-feet over the previous year. During the water year 1949-50, the San Diego Aqueduct operated at full capacity, delivering approximately 70,000 acre-feet of Colorado River water to the San Diego County Water Authority. The service area of the Metropolitan Water District was enlarged in November, 1950, with the annexation of the Pomona Valley Municipal Water District, comprising an area of 84,500 acres.

Generally, ground water levels have continued to decline over the southern portion of the State at an alarming rate, with levels in many of the major ground water basins being at a record low. Sea water continued to intrude into many of the coastal ground water basins where ground water levels were below sea level.

Authorization

The Legislature, by Chapter 832, Statutes of 1929, requested that exploration and investigation be conducted to formulate plans for the conservation, development, and utilization of the water resources of California. One of the reports prepared by the Division of Water Resources under this Chapter was Bulletin No. 32 published in 1930. This bulletin entitled "South Coastal Basin", was a progress report consisting of articles by the technical heads of leading public agencies concerned with water problems in the area. As a result of the recommendation made in Bulletin No. 32 that further hydrologic investigations be made, the Division of Water Resources was authorized to undertake a continuing study now known as the Southern California Area Investigation. This report is one of a series issued under that investigation.

Prior Reports

As part of the investigation, Bulletin No. 39 was published in 1932, containing "Records of Ground Water Levels at Wells". Since 1932, water levels at selected wells have been published annually in Bulletins Nos. 39-A through

39-R. The locations and descriptions of the wells referred to in the earlier bulletins were published in Bulletin No. 39, and are shown on Maps 1 through 8, accompanying that bulletin. The locations and descriptions of wells in the San Jacinto and Antelope Valleys were first published in Bulletin No. 39-J, and are shown on Maps 9 through 11 included in that bulletin.

Seasonal precipitation data from United States Weater Bureau records, as well as from records at stations not included in official publications of that agency, were first published in Bulletin 39-A and have been incorporated in all subsequent publications of the series. Monthly records from a few key United States Weather Bureau stations were first published in Bulletin No. 39-D. A map showing the location of precipitation stations for which seasonal records are published was included in Bulletin No. 39-A.

Numerous other bulletins have been published by the Division of Water Resources from 1930 to date which include data on water use, ground water levels, quality of water, value and cost of water for irrigation, water losses and evaporation data, underground geology, and evaluation of overdraft on ground water basins in southern California. These bulletins include:

- California State Department of Public Works, Division of Water Resources. "South Coastal Basin, A Symposium". Bulletin No. 32. 1930.
- California State Department of Public Works, Division of Water Resources. "Rainfall Penetration and Consumptive Use of Water in Santa Ana River Valley and Coastal Plain". Bulletin No. 33. 1930.
- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Quality of Irrigation Waters". Bulletin No. 40. 1933.
- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Detailed Analyses Showing Quality of Irrigation Waters". Bulletin No. 40-A. 1933.

- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Value and Cost of Water for Irrigation in Coastal Plain of Southern California". Bulletin No. 43. 1933.
- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Water Losses Under Natural Conditions from Wet Areas in Southern California". Bulletin No. 44. 1933.
- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Geology and Ground Water Storage Capacity of Valley Fill". Bulletin No. 45. 1934.
- California State Department of Public Works, Division of Water Resources. "South Coastal Basin Investigation, Overdraft on Ground Water Basins". Bulletin No. 53. 1947.
- California State Department of Public Works, Division of Water Resources. "Southern California Area Investigation, Memorandum Report on Water Conditions in Antelope Valley in Kern, Los Angeles and San Bernardino Counties". February, 1955.

Scope of Report

At its inception, the Southern California Area Investigation was concerned with the problems of water supply in the Santa Ana, San Gabriel, and Los Angeles River Valleys and the West and South Coastal Plains, and early reports of the Bulletin No. 39 series were limited to publication of records of ground water levels in those areas. Subsequently, precipitation records were added and the area extended to include the San Jacinto and Antelope Valleys. In 1948, the bulletin was expanded to include a general water supply summary for the southern portion of the State, containing information on precipitation, runoff, reservoir storage, importations, water quality, and changes in ground water levels. This report includes, in addition to a water supply summary for the period October 1, 1949, through September 30, 1950 a compilation of precipitation records for the period

July 1, 1949, through June 30, 1950, and records of ground water levels for the 1950 calendar year.

The data are presented under four chapter headings as follows:

(1) Introduction, (2) Water Supply, (3) Records of Ground Water Levels,
and (4) Precipitation Records. Fifteen tables summarizing water supply data
are included with the text of Chapter II, and two plates pertaining to ground
water data are bound at the end of the report.

CHAPTER II. WATER SUPPLY

Precipitation

The primary source of replenishment of the ground water basins in southern California is direct precipitation on overlying lands and percolation of runoff from precipitation on tributary hills and mountains. The amount of precipitation varies greatly from year to year, resulting in variations in the accretions to the ground water. Near Riverside where the Santa Ana Mountains interfere with the movement of air from the ocean toward the mountains to the north, mean seasonal depth of precipitation is only 11 inches, as compared with 24 inches at about the same elevation in the San Gabriel Valley, where there is relatively little interference from the low hills which bound it on the south. Mean seasonal depth of precipitation increases from about 10 to 15 inches along the coast to 30 to 45 inches near the crest of the mountains.

Precipitation indices for selected areas in southern California during the period July, 1949, through June, 1950, are shown in Table 1. These indices are arithmetical averages of the precipitation indices for several stations within the area, and are based on the 50-year mean for 1897-98 through 1946-47. No major storms occurred during the year. Seasonal precipitation records for individual stations are tabulated in Chapter IV.

Runoff

Runoff from mountain and hill areas, as stated, is a major source of replenishment of the ground water supply. A large portion of this runoff is impounded behind dams, to be later released to percolate to the underground basins, where it remains in storage for future use. Some of the runoff which occurs from precipitation on the valley floor areas also percolates to the ground water supply, although the major portion of such runoff wastes to the ocean.

The runoff in southern California in 1949-50 was below normal for the sixth consecutive season. Runoff in selected rivers and creeks in southern California is shown in Table 2, together with a comparison of mean, maximum, and minimum runoff for each station.

c. Mean for periods from 1912-13 through 1927-28, and from 1936-37 through 1946-47.

Storage in Surface Reservoirs

The amount of water in storage in surface reservoirs at the end of the water year 1949-50 was, in most cases, far less than the total capacity of the reservoirs. Water stored in Lake Henshaw, built in 1923, amounted to only three per cent of the total reservoir capacity, and the amount in storage in other reservoirs, not impounding imported water, was generally less than 20 per cent of the total storage capacity. Table 3 shows the amounts of storage in 21 reservoirs in, or supplying water to, southern California on September 30, 1950.

Importations

Owens River and Mono Basin

The Los Angeles Department of Water and Power obtains a large portion of the water supplied to the City of Los Angeles from Owens Valley and Mono Basin. Development of this supply was initiated many years ago when it became apparent that local supplies would not be sufficient to meet the demands of increasing population and industrial expansion. The City first obtained water from Owens Valley in 1913 and from Mono Basin in 1940. Water is stored in Grant Lake, Lake Crowley, and Haiwee Reservoirs in Mono and Inyo Counties and brought to Los Angeles through the 233-mile long Los Angeles Aqueduct which terminates in San Fernando Valley. During 1949-50 305,400 acre-feet of water, or 75 per cent of the total water imported, purchased, or produced locally by the City in that year, were imported from Owens River and Mono Basin.

Colorado River

Even with water from Owens River and Mono Basin, it became apparent in the early twenties that southern California would need more water. For this additional supply, attention was turned to the largest stream in the southwest, the Colorado River. In 1923, City of Los Angeles commenced a preliminary study of the River as a source of supply, and a few years later preliminary surveys were conducted. In 1928, The Metropolitan Water District of Southern California was formed, and in 1930 it took over all engineering and other work from the City. Construction of the Colorado River Aqueduct began in 1932, and Pasadena received the first delivery of softened Colorado River water in June, 1941. In the seasonal year 1949-50, a total of 65,600 acre-feet of softened and 98,200 acre-feet of unsoftened water were delivered by the Metropolitan Water District, which at that time consisted of 16 cities and districts. Of the 98,200 acre-feet of unsoftened water, 70,300 acre-feet

were supplied to the San Diego County Water Authority. Approximately 183,200 acre-feet, representing about 15 per cent of the 1,212,000 acre-foot per year right of The Metropolitan Water District of Southern California to waters of the Colorado River, were diverted at Lake Havasu.

Quality of Water

The Division of Water Resources has, since 1931, conducted a program of sampling and analyzing surface and ground waters in the southern California area. Most of these samples have been analyzed in the laboratory of the University of California, Citrus Experiment Station, in Riverside.

In general, ground and surface water mineral quality remained suitable for domestic, industrial, and agricultural uses in 1950, except in certain coastal ground water basins where sea-water intrusion had occurred. If, over a long period of time, conditions are such that extractions from a basin bordering the ocean exceed net recharge to the basin or the aquifer's water transmitting capacity under the existing hydraulic gradient, a landward hydraulic gradient may be formed and the possibility of sea-water intrusion exists. The intrusion of sea water into certain coastal aquifers has resulted in the degradation of ground water quality and, in some cases, the abandonment of wells valued at thousands of dollars. Evidence of sea-water intrusion exists in the following ground water basins:

- 1. Oxnard Plain Basin
- 2. West Coast Basin
- 3. East Coastal Plain Pressure Area
- 4. Santa Margarita Valley
- 5. San Luis Rey Valley
- 6. Mission Valley

Analyses of samples from key wells and surface sampling points are shown in Tables 4 and 5.

Changes in Ground Water Levels

The elevations of ground water levels in some basins reached record lows in 1950 and remained below sea level in several coastal basins. Changes in ground water level elevations between the fall of 1949 and the fall of 1950, and maximum and minimum water level elevations observed during the period of record at selected wells are presented in Tables 6 through 15. Plate 1 shows the locations within ground water basins of selected wells for which fluctuations of ground water levels are shown on Plate 2. Presented herein is a brief summary of ground water conditions in certain basins in the Antelope Valley and South Coastal Area.

Antelope Valley

Ground water levels have steadily declined in Antelope Valley for the past quarter century, indicating that net extractions have continuously exceeded the replenishment of the ground water supply. Observed depths to ground water increased an average of five feet between the fall of 1949 and the fall of 1950, with levels in some areas being as much as 270 feet below ground surface. Table 6 presents changes in ground water level elevations at 19 wells.

Santa Clara River Valley

Oxnard Plain Basin. The Oxnard Plain Basin is supplied principally by underflow from Oxnard Forebay Basin. Ground water levels in most of the pressure area remained below sea level in 1950, permitting sea-water intrusion, which was first noted in this region in 1932, to continue. Some ground water levels dropped to over 40 feet below sea level, and the observed net ground water level drop occurring between the fall of 1949 and the fall of 1950 was approximately five feet. The trough in the piezometric surface was observed about two to three miles inland from the coast in 1950.

Oxnard Forebay Basin. The Oxnard Forebay Basin is replenished largely by natural percolation in the channel of Santa Clara River and by off-channel water spreading conducted by the Santa Clara Water Conservation District at grounds near Saticoy. In 1950, ground water levels in this

basin dropped to, or approached, the lowest elevations of record. Ground water level observations indicate that about a six-foot net drop occurred in the basin between the fall of 1949 and the fall of 1950.

Observed changes in ground water level elevations in the major ground water basins in Ventura County are presented in Table 7.

San Fernando Valley

Ground water levels in the San Fernando Valley continued to drop for the sixth consecutive year, although, as shown on Plate 2, ground water level elevations at some wells were lower in 1931. During the seasonal year 1949-50, the observed average net drop in ground water levels at the wells listed in Table 8 was about three feet.

San Gabriel Valley

Raymond Basin Area. Since 1944, ground water levels underlying

exhibited little change, while water levels at some wells in the southern part of the subarea, near the Raymond fault, have risen over 100 feet. This general lack of lowering of ground water levels is due principally to the increased supply of imported waters for the rapidly expanding development, lack of substantial increase in sewage outflow, and the reduction of ground water extractions by Court decree.

Ground water levels in the Santa Anita Subarea commenced to drop in 1947, attained a record low in 1949, and tended to stabilize during 1950. The net lowering of ground water levels since 1947, as compared to the adjacent Pasadena Subarea, may be attributed to the absence of importations. Relatively small amounts of replenishment and extraction cause large monthly fluctuations of ground water levels due to the limited storage capacity of the basin. This phenomenon is illustrated by the hydrographs of wells Nos. C-99, C-130, and C-130a included on Plate 2.

Main San Gabriel Basin. Ground water levels at well No. C-294a, as shown on Plate 2, have declined from about 325 feet above sea level in 1943 to approximately 258 feet above sea level in 1950, which is about equal to the lowest observed level of record.

Changes in ground water level elevations in selected basins in San Gabriel Valley are presented in Table 9.

Coastal Plain, Los Angeles County

Montebello Forebay Area. Since 1947, ground water levels in the Montebello Forebay Area have steadily dropped until, in 1950, depths to ground water at many wells were the greatest of record. The ground water level at well No. C-814, the hydrograph for which is shown on Plate 2,

dropped about 60 feet from 1947 through 1950. The Montebello Forebay Area is replenished largely by natural stream bed percolation in the channels of the Rio Hondo and San Gabriel River and by diversion of water released from upstream dams to the Los Angeles County Flood Control District's Rio Hondo and San Gabriel spreading grounds.

Central Coastal Plain Pressure Area. In this basin, which is supplied from underflow from the Montebello and Los Angeles Forebay Areas, pressure levels remained below sea level in most areas. In some areas this condition has persisted since 1937. In 1895, well No. C-926 was flowing, with an artesian head of 80 feet; but in 1950 the piezometric surface at this well was observed more than 50 feet below sea level, as shown on Plate 2. In recent years, ground water levels in the forebay areas have dropped and ground water extractions have increased in the pressure area, resulting in the steepening of the hydraulic gradient from the forebay areas to the centers of extraction in the pressure area.

West Coast Basin. The piezometric surface in this basin remained below sea level throughout the entire basin encouraging the further intrusion of sea water, which was first observed in the main acquifer in 1913. In 1950, the trough in the piezometric surface was six to nine miles inland from Santa Monica Bay and was more than 80 feet below sea level two miles northeast of Wilmington. The principal fresh water replenishment is underflow from the Central Coastal Plain Pressure Area across the Newport-Inglewood Uplift.

Table 10 presents ground water level elevations at 11 wells in Montebello Forebay Area, Central Coastal Plain Pressure Area, and West Coast Basin for the fall of 1950.

Upper Santa Ana Valley

Chino Basin. Since 1945, ground water levels at most wells have steadily declined, with some levels dropping below the previously recorded lowest elevation. The water level at well No. D-743z has dropped approximately 40 feet since 1931; however, the level at well No. D-909 has only lowered about 11 feet since that date, presumably due to the proximity of the Santa Ana River, three miles to the south.

Bunker Hill Basin. Ground water levels continued to decline in Bunker Hill Basin, with levels at some wells in 1950 being below the lowest observed previous elevations. The water level at well No. E-109 dropped about 60 feet from 1943 through 1950, as depicted on Plate 2. The average ground water level decline in the Basin from the fall of 1949 to the fall of 1950 was approximately five feet. Table 11 lists elevations of ground water levels at 12 wells in the Upper Santa Ana Valley for the fall of 1949 and the fall of 1950.

Coastal Plain, Orange County

East Coastal Plain Pressure Area. The elevation of the piezometric surface throughout most of this area continues to be below sea level. The trough in the piezometric surface remained about midway between the coast line and the City of Santa Ana, with some levels along the trough being 30 feet below sea level in 1950. Evidence of sea-water intrusion was first observed in this basin in 1927 and the intrusion is continuing, with the farthest inland advance being noted in the Talbert zone in the Santa Ana gap. The replenishment of the pressure area, largely from the Santa Ana Forebay Area, has, in recent years, been less than the extractions from the area and has resulted in a continual drop of ground water levels.

Santa Ana Forebay Area. During 1950, the elevations of ground water levels underlying the Santa Ana Forebay Area dropped below sea level for the first time. Ground water levels in wells Nos. C-1124b, C-1129j, and C-1129m dropped below their lowest previously recorded elevations, declining over 100 feet since 1917, as shown on Plate 2. This forebay area is supplied largely by percolation from the Santa Ana River, including Colorado River water which was first discharged into the river channel in 1949. The changes in ground water level elevations at key wells in the pressure area between the fall of 1949 and the fall of 1950 are presented in Table 12.

San Jacinto Basin

Ground water levels in most of the basin have declined for seven consecutive years, and water levels underlying the area northwest of Lakeview have exhibited a general downward trend since 1915, as illustrated by the water level fluctuations at well No. 45/2W-7A shown on Plate 2.

Depths to ground water vary from approximately 15 feet near the San Jacinto River, southeast of Moreno, to about 300 feet, southwest of Valle Vista.

Natural recharge of the ground water basin by percolation in the San Jacinto River channel is augmented by spreading operations conducted adjacent to the river bed northeast of Valle Vista. Due to the subnormal runoff in the San Jacinto River in 1949-50, only about 90 acre-feet of water were diverted from the river and spread during the year. Ground water level elevations at 15 wells are shown in Table 13.

San Luis Rey Valley

Ground water levels continued to decline throughout the coastal portion of the valley, dropping about three feet since last fall, with some water levels north of Oceanside and southwest of San Luis Rey dropping to 15 feet below sea level in 1950. The intrusion of sea water, first observed in this basin in 1938, continued and has caused the abandonment of several wells in recent years. Table 14 lists ground water level elevations at certain key wells.

Tia Juana Basin

Ground water levels continued to decline in this basin, with some levels dropping below sea level in the western portion of the basin in 1950. Data in Table 15 indicate that ground water levels have dropped an average of about one foot since the fall of 1949.

CHAPTER III. RECORDS OF GROUND WATER LEVELS

A tabulation of distance to water surface for approximately 1,000 wells in Los Angeles, San Gabriel, and Santa Ana River Basins and in Antelope Valley is presented on the pages that follow. These records are a continuation of those published in previous reports of the Bulletin 39 series.

Following is a list of abbreviations used in this bulletin:
D.W.R Division of Water Resources
L.A. Co. F.C.D Los Angeles County Flood Control District
L.A.D.W. & P Los Angeles Department of Water & Power
L.B.W.D Long Beach Water Department
